

US008380244B2

(12) United States Patent

Gorsuch

(54) DUAL MODE UNIT FOR SHORT RANGE, HIGH RATE AND LONG RANGE, LOWER RATE DATA COMMUNICATIONS

- (75) Inventor: **Thomas E. Gorsuch**, Merritt Island, FL (US)
- (73) Assignee: **IPR Licensing, Inc.**, Wilmington, DE (US)
- (*) Notice: Subject to any disclaimer, the term of this patent is extended or adjusted under 35 U.S.C. 154(b) by 0 days.

This patent is subject to a terminal disclaimer.

- (21) Appl. No.: 12/615,098
- (22) Filed: Nov. 9, 2009

(57) ABSTRACT

A technique for communication with a local area network (LAN) via a wireless connection determines whether a first short-range, high-speed, wireless communication path is available and connects to the LAN using a longer range, lower speed wireless communication path if the short-range, highspeed wireless communication path is not available. The lowrange, high-speed wireless communication path is a wireless communication path is a wireless LAN connection such as an IEE 802.11-compliant wireless LAN and the long-range, low-speed wireless communication mode is a cellular CDMA-type connection. Determining whether the first IEEE 802.11 mode is available can be done by detecting a beacon signal, or transmitting a probe request message and detecting a probe response message in response to the probe request, indicating the presence or availability of the short-range, high-speed wireless communication path. Alternatively, the availability of short-range, high-speed wireless communication path can be detected by simply detecting activity on it.

ETSI GSM European Standard (Telecommunications Series)—Draft EN 301 344 V6.4.0 (Aug. 1999). Digital cellular telecommunications sytem (Phase 2+); General Packet Radio Service (GPRS); Service description; Stage 2 (GSM 03.60 version 6.4.0 Release 1997).

ETSI GSM European Standard (Telecommunications Series)—EN 301 349 V7.5.0 (Jul. 2000). Digital cellular telecommunications system (Phase 2+); General Packet Radio Service (GPRS); Mobile Station (MS)—Base Station System (BSS) interface; Radio Link Control/Medium Access Control (RLC/MAC) protocol (GSM 04.60 version 7.5.0 Release 1998).

ETSI GSM Technical Specification—ETSI TS 101 350 V7.0.0 (Jul. 1999). Digital cellular telecommunications system (Phase 2+); General Packet Radio Service (GPRS); Overall description of the GPRS radio interface; State 2 (GSM 03.64 version 7.0.0 Release 1998).

ETSI GSM Technical Specification—GSM 02.60 V7.0.0 (Apr. 1998). Digital cellular telecommunications system (Phase 2+); General Packet Radio Service (GPRS); Service description; Stage 1 (GSM 02.60 version 7.0.0 Release 1998).

ETSI GSM Technical Specification—GSM 04.01 V5.0.0 (Nov. 1996). Digital cellular telecommunications system; Mobile Station—Base Station System (MS-BSS) interface General aspects and principles (GSM 04.01).

ETSI GSM Technical Specification—GSM 05.01 V7.0.0 (1999-03). Digital cellular telecommunications system (Phase 2+); Physical layer on the radio path; General description (GSM 05.01 version 7.0.0 Release 1998).

ETSI GSM Technical Specification—TS 100 573 V6.1.1 (1998-07). Digital cellular telecommunications system (Phase 2+); Physical layer on the radio path; General description (GSM 05.01 version 6.1.1 Release 1997).

ETSI GSM Technical Specification—TS 100 939 V6.1.0 (1998-07). Digital cellular telecommunications system (Phase 2+); Mobile radio interface signalling layer 3; General aspects (GSM 04.07 version 6.1.0 Release 1997).

ETSI GSM Technical Specification—TS 100 939 V7.1.0 (1999-08). Digital cellular telecommunications system (Phase 2+); Mobile radio interface signalling layer 3; General aspects (GSM 04.07 version 7.1.0 Release 1998).

ETSI GSM Technical Specification—ETSI TS 101 113 V7.2.0 (1999-08). Digital cellular telecommunications system (Phase 2+); General Packet Radio Service (GPRS); Service description; Stage 1 (GSM 02.60 version 7.2.0 Release 1998).

ETSI GSM European Telecommunication Standard—Draft prETS 300 940, Seventh Edition (Jul. 1999). Digital cellular telecommunications system (Phase 2+); Mobile radio interface; Layer 3 specification (GSM 04.08 version 5.13.0 Release 1996).

ETSI GSM European Telecommunication Standard—ETS 300 910, Seventh Edition (Mar. 1999). Digital cellular telecommunications system (Phase 2+); Radio transmission and reception (GSM 05.05 version 5.10.0 Release 1996).

BACKGROUND OF THE INVENTION

The widespread availability of personal computers at low cost has led to a situation where the general public increas-10 ingly demands access to the Internet and other computer networks. A similar demand exists for wireless communications in that the public increasingly demands that cellular telephones be available at low cost with ubiquitous coverage.

As a result of its familiarity with these two technologies, 25 the general population now increasingly wishes to not only access computer networks, but to access such networks in wireless fashion as well. This is of particularly concern to users of portable computers, laptop computers, hand-held personal digital assistants (PDAs) and the like, who would 30 prefer and indeed now expect to be able to access such networks with the same convenience they have grown accustomed to when using their cellular telephones.

Unfortunately, there still is no widely available satisfactory solution for providing low cost, broad geographical coverage, 35 high speed access to the Internet and other networks using the existing wireless infrastructure which has been built at some expense to support cellular telephony. Indeed, at the present time, the users of wireless modems that operate with the existing cellular telephone network often experience a difficult time when trying to, for example, access the Internet to view web pages. The same frustration level is felt in any situation when attempting to perform other tasks that require the transfer of relatively large amounts of data between computers. 45

This is at least in part due to the architecture of cellular telephone networks, which were originally designed to support voice communications, as compared to the communications protocols in use for the Internet, which were originally optimized for wireline communication. In particular, the protocols used for connecting computers over wireline networks do not lend themselves well to efficient transmission over standard wireless connections.

For example, cellular networks were originally designed to deliver voice grade services, having an information band-55 width of approximately three kilohertz (kHz). While techniques exist for communicating data over such radio channels at the rate of 9600 kilobits per second (kbps), such low frequency channels do not lend themselves directly to transmitting data at rates of 28.8 kbps or even the 56.6 kbps that is now 60 commonly available using inexpensive wireline modems. These rates are presently thought to be the minimum acceptable data rates for Internet access.

This situation is true for advanced digital wireless communication protocols as well, such as Code Division Multiple 65 Access (CDMA). Even though such systems convert input voice information to digital signals, they too were designed to

provide communication channels at voice grade bandwidth. As a result, they use communication channels that may exhibit a bit error rate (BER) as high as one in one thousand bits in multipath fading environments. While such a bit error rate is perfectly acceptable for the transmission or voice signals, it becomes cumbersome for most data transmission environments.

Unfortunately, in wireless environments, access to channels by multiple subscribers is expensive and there is competition for them. Whether the multiple access is provided by the traditional Frequency Division Multiple Access (FDMA) using analog modulation on a group of radio carriers, or by newer digital modulation schemes that sharing of a radio carrier using Time Division Multiple Access (TDMA) or Code Division Multiple Access (CDMA), the nature of the cellular radio spectrum is such that it is a medium that is expected to be shared. This is quite dissimilar to the traditional environment for data transmission, in which the wireline medium is relatively inexpensive to obtain, and is therefore not typically intended to be shared.

On the other hand, wireless local area networks (W-LANs) have been developed to allow communications between users over a relatively small range without the need for a physical connection, or alternatively, to allow communications between a wired LAN and wireless users. W-LANs typically have a much smaller range and higher data rates.

A newly accepted standard, IEEE 802.1 1, specifies a protocol for the media access control (MAC) and physical (PHY) layers of a wireless LAN. As with cellular systems, a W-LAN connection can be handed off from one area of coverage (a "basic service set" in IEEE 802.1 1 parlance) to the next. A good description of wireless LANs, and the IEEE 802.1 1 standard in particular, may be found in Geier, J., Wireless LANs (Macmillan Technical Publishing, 1999).

SUMMARY OF THE INVENTION

Wireless LANs are generally private networks, that is they are installed, owned, and maintained by a private party, such as a business, educational institution or home owner. Such networks are therefore generally cheaper to access than long range networks which utilize shared public access frequencies licensed by a government authority to complete a connection, and which generally require subscriber fees.

In addition, W-LANs typically operate at a much faster data rate than the long range network. However, as the word "local" implies, the range of a W-LAN is rather limited typically tens or hundreds of feet, as compared to several miles for a long range cellular telephone network.

It would therefore be desirable to have a device which can automatically select the cheaper and faster W-LAN when possible, e.g., when within its range, and to resort to the long range cellular network when access to the W-LAN is not possible or practical. Previously, two devices would have been required, one for accessing the WLAN and one for accessing the long range network. At best, these two devices could fit into two slots in, for example, a laptop computer, requiring the user to select, either through software or hardware, which device, and hence, which network to access. The user might typically then have to disconnect one of the devices to install the other, and manually reconfigure the computer.

The present invention, on the other hand, is a single device which connects directly to a W-LAN using a protocol such as IEEE 802.1 1 when such a connection is possible, and automatically reverts to connecting to the long range network only when out of range of the W-LAN base stations. Thus, the same equipment can be used without any reconfiguration and even without the knowledge of the user. For example, when the user is on a company campus and within range of the less expensive, faster W-LAN, the user's laptop or PDA automatically communicates with the W-LAN. If the user leaves the 5 office, for example, for lunch, or at the end of the day, heads home, the same laptop or PDA, being out of range of the W-LAN, will automatically communicate instead with the wider range, more expensive cellular network.

Therefore, the present invention is also a method which 10 uses a first wireless digital communication path and a second wireless digital communication path for coupling data communication signals with a local wireless transceiver at a first site. The second digital communication path provides wider coverage and a slower communication rate than the first digi-15 tal communication path. The local wireless transceiver conducts wireless communications with a remote wireless transceiver at a second site.

One of the wireless communication path is selected upon a request to establish a communication session between the 20 first and second sites by first determining whether the first wireless digital communication path is available.

In one embodiment, the first wireless communication path comprises a wireless LAN connection, preferably using carrier sense multiple access with collision avoidance 25 (CSWCA), preferably according to the IEEE 802.1 1 specification. The second wireless communication path comprises a cellular connection. Access costs associated with the first wireless communication path are smaller than access costs associated with the second wireless communication path. 30 Preferably, access to the first wireless communication path is essentially free, excluding expenses such as set-up and maintenance costs, while access to the second wireless communication path can be subscription-based.

The local wireless transceiver can be a single transceiver 35 which is capable of communicating with a second site or destination over both wireless communication paths. Alternatively, the local wireless transceiver can comprise two transceivers, one for each communication path.

In one embodiment, the first wireless communication path 40 is a private network. Conversely, the second wireless communication path can be a public network, in which channels are allocated centrally.

In one embodiment, the step of determining whether the first wireless communication mode is available is performed 45 by passive scanning, such as by detecting a beacon signal. In another embodiment, active scanning is used, for example, by transmitting a probe request message and detecting a probe response message in response to the probe request which indicates the presence of the first wireless communication 50 path. In yet another embodiment, determining whether the first wireless communication path is available comprises simply detecting activity on the first wireless communication path.

If the first wireless digital communication mode is avail- 55 able, a communication session between the first and second sites using the first wireless digital communication path is established.

On the other hand, if the first wireless digital communication path is not available, a communication session between 60 the present invention. the first and second sites using the second wireless digital communication path is established. In this case, the local wireless transceiver is controlled to make it appear to the second wireless digital communication path as though the bandwidth were continuously available during the communi- 65 FIG. 1 is a block diagram of a system 10 for implementing cation session, irrespective of any actual need to transport data communication signals between said first and second

4

sites. In the absence of such a need to transport data communication signals between the first and second sites, the bandwidth is made available for wireless communication by other wireless transceivers.

In one preferred embodiment, the second wireless digital communication path is provided by establishing a logical connection using a higher layer protocol, such as a network layer protocol, from a subscriber unit, such as may be connected to a portable computer node, to an intended peer node, such as another computer. The network layer logical connection is made through a wireless channel which provides a physical layer connection between the portable computer node, through a base station, and the intended peer node. In response to relatively low utilization of the wireless channel, the physical layer channel is released while maintaining the appearance of a network layer connection to the higher level protocols.

This has two consequences. First, it frees wireless channel bandwidth for use by other subscriber units, without the overhead associated with having to set up an end to end connection each time that data needs to be transferred. In addition, and perhaps more importantly, by allocating wireless channels only when needed, the bandwidth necessary to provide a temporary but very high speed connection is available at critical times. These may occur, for example, when a particular subscriber unit requests that a web page file be downloaded from the Internet.

More specifically, the technique, which is here called spoofing, involves stripping off the lower layers of the protocol while reformatting higher layer messages for transmission using a more efficient CDMA based encapsulated protocol.

BRIEF DESCRIPTION OF THE DRAWINGS

The foregoing and other objects, features and advantages of the invention will be apparent from the following more particular description of preferred embodiments of the invention, as illustrated in the accompanying drawings in which like reference characters refer to the same parts throughout the different views. The drawings are not necessarily to scale, emphasis instead being placed upon illustrating the principles of the invention.

FIG. 1 is a block diagram of a system in which a portable device such a laptop computer is making use of a protocol converter according to the invention to connect to a computer network over a wireless cellular link.

FIG. 2 is a diagram depicting how network layer data frames are divided among multiple physical links or channels

FIG. 3 is a more detailed diagram showing how network layer frames are divided into subframes by a protocol converter located at a sender.

FIG. 4 is a continuation of the diagram of FIG. 3.

DETAILED DESCRIPTION OF THE INVENTION

Turning attention now to the drawings more particularly, high speed data communication over a cellular link according to the invention. The system 10 consists of a remote or subscriber unit **20**, multiple bi-directional communication links **30**, and a local or service provider unit **40**.

The subscriber unit 20 connects to terminal equipment 22 such as a portable or laptop computer, hand held Personal Digital Assistant (PDA) or the like, via a computer interface 524 such as a modem. The interface 24 in turn provides data to a protocol converter 25, which in turn provides data to a multichannel digital transceiver 26 and antenna 27.

The interface **24** receives data from the computer **20**, and together with appropriate hardware and/or software, converts 10 it to a format suitable for transmission such as in accordance with known communication standards. For example, the interface **24** may convert data signals from the terminal equipment **22** to a wireline physical layer protocol format such as specified by the Integrated Services Digital Network (ISDN) 15 standard at rates of 128 kbps, or the Kflex standard at rates of 56.6 kbps. At a network layer, the data provided by the interface **24** is preferably formatted in a manner consistent with suitable network communication protocols such as TCP/IP to permit the terminal equipment **22** to connect to other computers over networks such as the Internet. This description of the interface **24** and protocols is exemplary only and it should be understood that other protocols can be used.

The protocol converter **25** implements an intermediate protocol layer suitable for converting the data provided by the 25 interface **24** to a format appropriate for the multichannel transceiver **26** according to the invention, and as is described in greater detail below.

The multichannel digital transceiver **26** provides access to one or more physical communication links such as the illustrated radio channels **30**. The physical links are preferably known wireless communication air interfaces using digital modulation techniques such as Code Division Multiple Access (CDMA) standard specified by IS-95. It should be understood that other wireless communication protocols and other types of links **30** may also be used to advantage with the invention.

The channels **30** represent one or more relatively slower communication channels, such as operating at a 9.6 kbps rate typical of voice grade communication. These communications channels may be provided by a single wide bandwidth CDMA carrier such as having a 1.25 MegaHertz bandwidth, and then providing the individual channels with unique orthogonal CDMA codes. Alternatively, the multiple channels **30** may be provided by single channel communication such as provided by other wireless communication protocols. However, what is important is that the net effect is that the channels **30** represent multiple communication channels that may be adversely effected by significant bit error rates that are unique to each link **30**.

An "error" as described herein is a bit error perceived at the higher layer such as the network layer. The invention only strives to improve the system level bit error rate, and does not attempt to guarantee absolute data integrity.

On the local provider unit, the service provider equipment 55 40 may for example be implemented at a wireless Internet Service Provider (ISP) 40-1. In this case, the equipment includes an antenna 42-1, a multichannel transceiver 44-1, a protocol converter 46-1, and other equipment 48-1 such as modems, interfaces, routers, and the like which are needed for 60 the ISP to provide connections to the Internet 49-1.

At the ISP **40-1**, the multichannel transceiver **44-1** provides functions analogous to the multichannel transceiver **26** of the subscriber unit, but in an inverse fashion. The same is true of the protocol converter **46-1**, that is, it provides inverse functionality to the protocol converter **25** in the subscriber unit **20**. The ISP **40-1** accepts data from the protocol converter **46-1** in

the TCP/IP frame format and then communicates such data to the Internet **49-1**. It should be understood that the configuration of the remaining ISP equipment **48-1** may take any number of forms such as a local area networks, multiple dial up connections, T1 carrier connection equipment, or other high speed communication links to the Internet **49-1**.

Alternatively, the provider 40 may function as a radio base station in a cellular telephone system to permit a dial-up connection between the terminal equipment 22 and a server 49-2. In this instance, the base station 40-2 includes an antenna 42-2, multichannel transceiver 44-2, and protocol converter 46-2 providing one or more connections to a public switched telephone network (PSTN) 48-2, and ultimately to the server 49-2.

In addition to the illustrated implementations **40-1**, **40-2**, there may be various other ways of implementing the provider **40** in order to provide a connection to data processing equipment from the terminal equipment **22**.

Attention is now turned to the functions of the protocol converters **25** and **46**, which can be thought of as an intermediate layer within the context of the Open System Interconnect (OSI) model for communication. In particular, the protocol converter provides a bandwidth management functionality **29** implemented between a physical layer such as that provided by the CDMA protocol in use with the multichannel transceivers **26** and a network layer protocol such as TCP/IP providing connections between the terminal equipment **22** and the Internet **49-1** or server **49-2**.

The bandwidth management functionality **29** preferably provides a number of functions in order to keep both the physical layer and network layer connections properly maintained over multiple communication links **30**. For example, certain physical layer connections may expect to receive a continuous stream of synchronous data bits regardless of whether terminal equipment at either end actually has data to transmit. Such functions may also include rate adaption, bonding of multiple channels on the links, spoofing, radio channel setup and takedown.

The present invention is more particularly concerned with the technique used by the protocol converters 25 and 46 for adjusting the frame size of individual channels used over each of the multiple links 30 in order to improve the effective throughput rate between a sender and a receiver in a bit error rate prone environment. It should be understood in the following discussion that the connections discussed herein are bidirectional, and that a sender may either be the subscriber unit 22 or the provider unit 40.

More specifically, the problem addressed by the present 50 invention is shown in FIG. **2**. The frame **60** as received at the receiver end must be identical to the frame **50** originating at the sender. This is despite the fact that multiple channels are used with much higher bit error rates, with the received frame **60** being transmitted reliably with a bit error rate of 10^{-6} or 55 better as is typically required in TCP/IP or other network layer protocols. The present invention optimizes the effective data throughput such that the received frames **60** are not affected by the experienced bit error rate performance of network layer connections.

It should be understood that another assumption is that the individual channels **30-1**, **30-2**... **30-N** may experience different bit error rate levels both over time and in an average sense. Although each of the channels **30** may operate quite similarly, given the statistical nature of errors, identical behavior of all of the channels **30** is not assumed. For example, a specific channel **30-3** may receive severe interference from another connection in a neighboring cell, and be

20

capable of providing only a 10^{-3} whereby other channels **30** may experience very little interference.

In order to optimize the throughput for the system 10 on a global basis, the invention also preferably optimizes the parameters of each channel 30 separately. Otherwise, a relatively good channel 30-1 might suffer down speed procedures required to accommodate a weaker channel 30-3.

It should also be understood that the number of channels **30** that may be needed to carry a single data stream such as a rate of 128 kbps at a given point in time may be relatively large. For example, up to 20 channels **30** may be assigned at a particular time in order to accommodate a desired data transfer rate. Therefore, the probability of significantly different characteristics in any given one of the channels **30** is high.

Turning attention now more particularly to FIG. 3, the operations of the protocol converter 25 or 46 at the sender will be more particularly described. As shown, the input frame 50 as received from the network layer is relatively large, such as for example 1480 bits long, in the case of a TCP/IP frame.

The input frame 50 is first divided into a set of smaller pieces 54-1, 54-2. The size of the individual pieces 54 are chosen based upon the optimum subframe size for each of the channels 30 available. For example a bandwidth management function may make only a certain number of channels 30 25 available at any time. A subset of the available channels 30 is selected, and then the optimum number of bits for each subframe intended to be transmitted over respective one of the channels, is then chosen. Thus, as illustrated in the figure, a given frame 54-1 may be divided into pieces associated with 30 four channels. At a later time, there may be nine channels 30 available for a frame, with different optimum subframe sizes for the piece 54-2.

Each of the subframes **56** consists of a position identifier **58***a*, a data portion **58***b*, and a trailer typically in the form of 35 an integrity checksum such as a cyclic redundancy check (CRC) **58***c*. The position identifier **58***a* for each subframe indicates the position within the associated larger frame **50**.

The subframes **56** are then further prepared for transmission on each channel **30**. This may be done by adding a 40 sequence number related to each channel at the beginning of each subframe **56**. The subframe **56** is then transmitted over the associated channel **30**.

FIG. 4 illustrates the operations performed at the receive side. The subframes 56 are first received on the individual 45 channels 30. A subframe 56 is discarded as received if the CRC portion 58c is not correct.

The sequence numbers **58***d* of the remaining frames **56** are then stripped off and used to determine whether any subframes **56** are missing. Missing subframes **56** can be detected 50 by comparing the received sequence numbers **58***d*. If a sequence number is missing, it is assumed that the associated subframe **56** was not received properly. It should be understood that appropriate buffering of data and subframes **56** is typically required in order to properly receive the subframes **55 56** and determine if there are any missing sequence numbers depending upon the transmission rates, number of channels **30** and propagation delays in effect.

Upon the detection of a missing subframe **56**, retransmission of the missed subframe is requested by the receiving end. 60 At this point, the transmitting end reperforms transmission of the missing subframe.

Once all of the subframes 56 are received, the position number 58a is used to arrange the data from the subframes 56in the proper order to construct the output received frame 60. 65

At this point, also, if any piece of the large output frame **60** is still missing, such as when an end of frame command is

encountered, retransmission of the corresponding subframe can also be requested at the indicated position, specifying a length for the missing piece.

Because of the use of both the position and sequence numbers, the sender and receiver know the ratio of the number of subframes received with errors to the number of frames received without errors. Also, the receiver and sender know the average subframe length for each channel. The optimum subframe size can thus be determined for each channel from these parameters as is described more fully in U.S. Pat. No. 6,236,647 filed on Feb. 24, 1998, entitled "Dynamic Frame Size Adjustment and Selective Reject On a Multi-Link Channel to Improve Effective Throughput and Bit Error Rate," incorporated herein by reference in its entirety, and assigned to Tantivy Communications Corp., the assignee of the present application.

FIG. 5 illustrates a short range, high speed wireless LAN (W-LAN) overlapping with a longer range, lower speed wireless cellular communication network ("long range network"). Specifically, within the longer range, lower speed system, which may be a digital cellullar mobile telephone system, there are multiple long range regions or "cells" **601** and **603** which provide coverage throughout a given physical area. The range or coverage for each cell **601**, **603** is on the order of, for example, greater than one mile radius.

A cellular base station **605** transmits and receives data through its antenna **171** to mobile units located within its associated cell **601**. The base station **605** is connected to a public network **619** such as the public switched telephone network (PSTN) or preferably a point of presence (POP) or other data connection **621** to the Internet.

Shown within the cell **601** associated with base station **605** is a wireless local area network (W-LAN) **607**. Several terminals or computers **609** are connected directly to the W-LAN **607**, including a gateway **609**A which is also connected to the public network **619** via any well-known means **621**. In addition, two wireless LAN hubs **611A**, **611B** are connected to the LAN **607**. Each wireless LAN hub **611** has a region of coverage **613A**, **613B**; the coverage area of the two hubs **611A**, **611B** may overlap as shown in FIG. **5**. The regions of coverage **613A**, **613B** are generally of the order of tens or hundreds of feet, which is significantly smaller than the cells **601**, **603** associated with the long range network. In this respect, it is particularly important to note that FIG. **5** is not drawn to scale.

Also shown are two subscriber units or terminals, such as portable computers, employing the present invention. The first terminal **615** is within range **613**A of a wireless LAN base station **611**, while the second terminal **617** is outside the range of either wireless LAN base station **611A**, **611**B but within the range **601** of the long range network base station **605**.

Because communication within the short range wireless LAN **613**A or **613**B is faster and less expensive as compared to the long range network, it is desirable to communicate using the short range path, i.e., the W-LAN protocol, rather than the more costly long range network, when a user's computer terminal **61 5** is within range of a WLAN base station **611**, i.e., within the region of coverage **613**A, **613**B.

On the other hand, it is desirable that a terminal such as terminal **617**, which is not within range of a wireless LAN base station **6 1 1**, automatically communicate through the long range network's base station **605**. Thus it is a primary feature of the present invention that a terminal such as **615** or **617** detects the presence or availability of a wireless LAN hub **61 1**A or **611**B, such as an EEE 802.1 1-compliant W-LAN hub. This can be done in several ways. For example, IEEE

802.1 1 specifies that a beacon frame should be transmitted at regular intervals. A terminal **6 15**, **6 1 7** can detect the beacon frame by waiting a minimum period of time equal to the beacon interval. See, for example, Geier, J., Wireless LANs, pages 137 and 149, (Macmillan Technical Publishing, 1999), incorporated herein by reference, which describes how a W-LAN beacon signal is formatted.

Alternatively, a terminal such as **615** may actively transmit a probe request frame. A wireless LAN base station **611** receiving such a probe request frame will respond with a probe response frame. Receipt of the probe response frame by the terminal **615** indicates accessibility of the wireless LAN, and the terminal **615** will use the wireless LAN and bypass the long range network.

If, on the other hand, no beacon is received within the specified time period or no probe response frame is returned from the base frame, as would be the case with terminal **617**, the terminal assumes that the wireless LAN base stations **611** are not accessible and instead communicates with the long ₂₀ range base station **605** using the long range network protocol rather than IEEE **802.11** protocol.

Yet another alternative is simply to listen for activity on the wireless LAN **611**. If no activity is heard, the terminal **615**, **617** assumes that the LAN is not accessible, and uses the long ²⁵ range communication system.

FIG. 6 shows a terminal 615 which includes a subscriber unit 101 incorporating the features of the present invention. A user at this terminal 615 desires to communicate with a second site using a portable computer 110, PDA or other similar device. The computer 1 10 is connected to the subscriber unit 101. For example, the subscriber unit 101 may be a PCMCIA card which plugs into a PCMCIA slot, or it may connect to the computer 110 with a modem cable.

35 The subscriber unit 101 itself preferably consists of an interface 120, a CDMA protocol converter 130 that performs various functions including spoofing 132 and bandwidth management 134 as described earlier, a CDMA transceiver 140, a W-LAN protocol converter 230, a W-LAN transceiver 40 240, a W-LAN detection circuit 201, path selection switches 211A, 211B, and a subscriber unit antenna 150. The various components of the subscriber unit 101 may be realized in discrete devices or as an integrated unit. For example, an existing conventional computer interface 120 such as the 45 PCMCIA, ISA bus, PC1 bus, or any other computer interface may be used together with existing transceivers 140, 240. In this case, the unique functions are provided entirely by the protocol converters 130, 230 which may be sold as separate devices, the W-LAN detection circuit 201 and the mode selec- 50 tion switches 211A, 211B.

Alternatively, the interface 120, protocol converters 130, 233, and transceivers 140,240 may be integrated as a complete unit and sold as a single subscriber unit device 101. Other types of interface connections such as Ethernet, ISDN, 55 or still other data connections may be used to connect the computing device 1 10 to the protocol converter 130.

The CDMA protocol converter 130 performs spoofing 132 and basic bandwidth management 134 functions. In general, spoofing 132 consists of insuring that the subscriber unit 101 60 appears, to the terminal equipment 1 10, to be connected to the public network 6 19 (FIG. 5) on the other side of the base station 605 at all times.

The bandwidth management function **134** is responsible for allocating and deallocating CDMA radio channels **160** as 65 required. Bandwidth management **134** also includes the dynamic management of the bandwidth allocated to a given

session by dynamically assigning sub-portions of the CDMA radio channels **160** in a manner using a protocol such as that described previously.

The CDMA transceiver **140** accepts the data from the protocol converter **130** and reformats this data in appropriate form for transmission through the subscriber unit antenna **150** over the radio link **160**. The CDMA transceiver **140** may operate over only a single 1.25 MHz radio frequency channel or, alternatively, may be tunable over multiple allocatable radio frequency channels.

CDMA signal transmissions are then received and processed by the base station equipment **605** (FIG. **5**). The base station **605** then couples the demodulated radio signals to, for example, the public network **619** in a manner which is well known in the art. For example, the base station **605** may communicate with the public network **619** over any number of different efficient communication protocols such as primary rate, ISDN, or other LAPD based protocols such as IS-634 or V5.2.

It should also be understood that data signals travel bidirectionally across the CDMA radio channels **160**. In other words, data signals received from the public network **619** are coupled to the portable computer **1 10** in a forward link direction, and data signals originating at the portable computer **110** are coupled to the public network **6 19** in a so-called reverse link direction.

Continuing to refer to FIG. 6 briefly, in the long range, lower data rate mode, the spoofing function 132 involves having the CDMA transceiver 140 loop back synchronous data bits to spoof the terminal equipment 110 into believing that a sufficiently wide wireless communication link 160 is continuously available. However, wireless bandwidth is allocated only when there is actual data present from the terminal equipment to the CDMA transceiver 140. Therefore, the network layer need not allocate the assigned wireless bandwidth for the entirety of the communications session. That is, when data is not being presented upon the terminal equipment to the network equipment, the bandwidth management function 134 deallocates initially assigned radio channel bandwidth 160 and makes it available for another transceiver and another subscriber unit 101.

W-LAN detection circuit **201** detects the presence or availability of a W-LAN base station **611** using, for example, one of the techniques previously discussed. If no W-LAN base station is detected, switches **211**A and **211**B are controlled by the detection circuit **201** such that the CDMA protocol converter **130** is switched in along with the CDMA transceiver **140**.

If, on the other hand, a W-LAN is detected, switches **211**A and **211**B are switched to the position shown to utilize the W-LAN protocol converter **230** and transceiver **240**, which are preferably IEEE 802.1 1-compliant. Note that the path switches **211** A, **21** 1B may be implemented in software or hardware, or a combination of hardware and software. Other functions may also be implemented in hardware and/or software which may further be shared by the W-LAN and CDMA sections where appropriate.

Furthermore, the long-range, low-speed CDMA path could be selected after failure to communicate over the short-range, high speed path for any reason, for example, the inability to successfully complete a communication after some predetermined time period.

While this invention has been particularly shown and described with references to preferred embodiments thereof, it will be understood by those skilled in the art that various

changes in form and details may be made therein without departing from the scope of the invention encompassed by the appended claims.

The invention claimed is:

- 1. A subscriber unit comprising:
- a cellular transceiver configured to communicate with a cellular wireless network via a plurality of assigned physical channels;
- an IEEE 802.11 transceiver configured to communicate 10 with an IEEE 802.11 wireless local area network; and
- a processor configured to maintain a communication session with the cellular wireless network in an absence of the plurality of assigned physical channels while the IEEE 802.11 transceiver communicates packet data with 15 the IEEE 802.11 wireless local area network.

2. The subscriber unit of claim **1**, wherein the packet data is transmission control protocol and Internet protocol (TCP/IP) packet data.

3. The subscriber unit of claim **1**, wherein the communi- 20 cation session is a transmission control protocol (TCP) layer session, an Internet protocol (IP) layer session, or a network layer session.

- 4. The subscriber unit of claim 1, further comprising:
- a detector configured to detect the IEEE 802.11 wireless 25 local area network; and
- a circuit configured to select the IEEE 802.11 transceiver in response to the detector detecting the IEEE 802.11 wireless local area network.

5. The subscriber unit of claim **4**, wherein the processor is 30 further configured to release the plurality of assigned physical channels.

6. The subscriber unit of claim 4, wherein the detector is configured to detect a beacon frame or a probe response frame received by the IEEE 802.11 transceiver from the IEEE 35 802.11 wireless local area network.

7. The subscriber unit of claim 1, wherein at least one of the plurality of assigned physical channels is a data channel.

8. The subscriber unit of claim **1**, wherein the cellular wireless network is a code division multiple access (CDMA) ⁴⁰ wireless network, and the cellular transceiver is a cellular code division multiple access (CDMA) transceiver.

9. The subscriber unit of claim **1**, wherein the cellular transceiver is further configured to transmit traffic data using a first physical channel and a second physical channel, 45 wherein transmission parameters associated with the first physical channel differ from transmission parameters associated with the second physical channel.

10. The subscriber unit of claim **1**, wherein the cellular transceiver is further configured to receive traffic data using a 50 first physical channel and a second physical channel, wherein transmission parameters associated with the first physical channel differ from transmission parameters associated with the second physical channel.

11. The subscriber unit of claim **1**, wherein the cellular ⁵⁵ transceiver is further configured to communicate with the cellular wireless network via a sub-frame that includes a sequence number and a data portion.

12. The subscriber unit of claim **11**, wherein the cellular transceiver is further configured to receive an indication of a 60 missing sub-frame and to retransmit the missing sub-frame.

13. The subscriber unit of claim **11**, wherein the sub-frame further includes an indication of a position of the sub-frame within a frame.

14. The subscriber unit of claim **1**, wherein the packet data 65 is communicated to the Internet via the IEEE 802.11 wireless local area network, and not via the cellular wireless network.

15. The subscriber unit of claim **1**, wherein the processor is further configured to allocate and deallocate at least one of the plurality of assigned physical channels.

16. The subscriber unit of claim 1, further comprising:

a detector configured to detect whether the IEEE 802.11 wireless local area network is available, wherein packet data is automatically communicated to the IEEE 802.11 wireless local area network when the IEEE 802.11 wireless local area network is available.

17. The subscriber unit of claim **16**, wherein the IEEE 802.11 transceiver is further configured to complete communicating packet data with the IEEE 802.11 wireless local area network.

18. The subscriber unit of claim **1**, wherein the processor is further configured to complete communicating packet data via the cellular wireless network after the IEEE 802.11 transceiver fails to complete communicating packet data with the IEEE 802.11 wireless local area network.

19. The subscriber unit of claim **1**, wherein the processor is further configured to automatically communicate with the cellular wireless network on a condition that the IEEE 802.11 wireless local area network is unavailable.

20. The subscriber unit of claim **19**, wherein the processor is configured to automatically communicate with the cellular wireless network by utilizing the communication session with the cellular wireless network.

21. The subscriber unit of claim **1**, wherein the processor is configured to release the plurality of assigned physical channels in response to a low utilization of the plurality of assigned physical channels or in response to a detection of the IEEE 802.11 wireless local area network.

22. The subscriber unit of claim **1**, wherein the packet data is transmission control protocol and Internet protocol (TCP/ IP) data.

23. A method for use in a dual mode subscriber unit, the method comprising:

- establishing a communication session with a cellular wireless network:
- maintaining the communication session in an absence of any physical channels associated with the cellular wireless network; and
- communicating packet data with an IEEE 802.11 wireless local area network while maintaining the communication session with the cellular wireless network.

24. The method of claim **23**, wherein the packet data is transmission control protocol and Internet protocol (TCP/IP) packet data.

25. The method of claim **23**, wherein the communication session is a transmission control protocol (TCP) layer session, an Internet protocol (IP) layer session, or a network layer session.

26. The method of claim 23, further comprising:

detecting the IEEE 802.11 wireless local area network; and communicating with the IEEE 802.11 wireless local area network in response to detecting the IEEE 802.11 wireless local area network.

27. The method of claim 26, further comprising:

releasing all assigned physical channels associated with the first cellular wireless network.

28. The method of claim **26**, wherein detecting the IEEE 802.11 wireless local area network comprises receiving a beacon frame or a probe response frame from the IEEE 802.11 wireless local area network.

29. The method of claim **23**, wherein at least one of the physical channels is a data channel.

30. The method of claim 23, wherein the cellular wireless network is a code division multiple access (CDMA) wireless network.

31. The method of claim **23**. further comprising:

transmitting traffic data to the cellular wireless network 5 using a first physical channel and a second physical channel, wherein transmission parameters associated with the first physical channel differ from transmission parameters associated with the second physical channel.

32. The method of claim 23, further comprising:

- receiving traffic data from the cellular wireless network using a first physical channel and a second physical channel, wherein transmission parameters associated with the first physical channel differ from transmission 15 parameters associated with the second physical channel.
- 33. The method of claim 23, further comprising:
- communicating with the cellular wireless network via a sub-frame that includes a sequence number and a data portion.

34. The method of claim 33, further comprising:

receiving an indication of a missing sub-frame from the cellular wireless network; and

retransmitting the missing sub-frame.

35. The method of claim $\tilde{33}$, wherein the sub-frame further $_{25}$ includes an indication of a position of the sub-frame within a frame.

36. The method of claim 23, wherein the packet data is communicated to the Internet via the IEEE 802.11 wireless

37. The method of claim 23, further comprising:

allocating and deallocating at least one physical channel associated with the cellular wireless network.

38. The method of claim 23, further comprising:

- detecting whether the IEEE 802.11 wireless local area network is available; and
- automatically communicating packet data with the IEEE 802.11 wireless local area network upon detection of the IEEE 802.11 wireless local area network being available.

39. The method of claim 38, wherein automatically communicating packet data includes completing communicating 10 packet data via the IEEE 802.11 wireless local area network.

40. The method of claim 23, further comprising: completing communicating packet data via the cellular wireless network after failing to complete communicating packet data via the IEEE 802.11 wireless local area

41. The method of claim 23, further comprising:

network.

automatically communicating with the cellular wireless network on a condition that the IEEE 802.11 wireless local area network is unavailable.

42. The method of claim 41, wherein automatically communicating with the cellular wireless network includes utilizing the communication session with the cellular wireless network.

43. The method of claim 23, further comprising:

releasing all assigned physical channels in response to a low utilization of the assigned physical channels or in response to a detection of the IEEE 802.11 wireless local area network.

44. The method of claim 23, wherein the packet data is local area network, and not via the cellular wireless network. 30 transmission control protocol and Internet protocol (TCP/IP) data.
